Abstract. A new scheme is presented for the accurate tracking control of robot manipulators. Based on the more general suction control methodology, the scheme addresses the following problem: Given the extent of parametric uncertainty (such as imprecisions or inertias, geometry, loads) and the frequency range of unmodeled dynamics (such as unmodeled structural modes, neglected time delays), design a nonlinear feedback controller to achieve optimal tracking performance, in a

Efficient Computation of the Jacobian for Robot Manipulators

Dynamics is the analysis of motion caused by forces. In addition to geometry, we now require parameters like mass and inertia to calculate the acceleration of bodies. Robot manipulators are often composed of several joints. Joints are composed of revolute (rotating) or prismatic (linear)

Abstract A more efficient method for computing the Jacobian matrix for robot manipulators is developed. Compared with the existing methods, the number of required numerical operations is greatly reduced, making the proposed technique the fastest or the least expensive one for any general N degrees-of-freedom manipulator.

Summary. The Inverse Kinematics (IK) problem of manipulators can be divided into two distinct steps: (1) Problem formulation, where the problem is

Developed into a form which can then be solved using various methods. (2) Problem solution, where the IK problem is actually solved by producing the values of different joint space variables (joint angles, joint velocities or joint accelerations).

We have covered several ways to generate motion trajectories for robot manipulators. Since trajectories are parametric, they give us analytical expressions for position, velocity, and acceleration...
